MSME owner earnings and cash headroom

$$OE = N + D + A - M - \Delta W$$

OE is estimated annual owner earnings; N is annual normalized net income after replacing owner labour; D is depreciation/amortisation already expensed; A is other justified noncash adjustment; M is annual maintenance investment; ΔW is an increase in required operating working capital. All are KES/year. A release of working capital is negative.

$$H = C + R - U - X - B, \quad H_{\text{reviewed}} = H - Q$$

H is dated headroom, C stated available cash, R additional confirmed collections, U listed due uses, X restricted cash, B the retained reserve and Q the disputed/uncollected amount counted in C or R. All are KES over the stated cash horizon. Subtract the proposed draw from reviewed H.

Thirteen-week operating cash planner

$$C_t = C_{t-1} + R_t + E_t + F_t - U_t$$

C_t is week-end cash; C_{t-1} is opening cash; R_t is operating cash received, E_t new owner funds, F_t new borrowing and U_t all scheduled cash uses. Values are KES in week t; t runs from 1 to 13.

$$\text{Reserve funding need} = \max\left(0, B - \min_{0 \leq t \leq 13} C_t\right)$$

B is the chosen KES reserve floor and C_0 opening unrestricted cash. This is the initial buffer required to cover the deepest forecast gap, assuming the remaining cash flows are unchanged.

Business cash stress and warning planner

$$C_t = C_{t-1} + R_t + E_t + F_t - U_t$$

All terms are KES for week t: closing cash C, operating receipts R, new owner funds E, new borrowing F and all cash uses U. Opening cash C_0 is unrestricted. No emergency financing is inserted automatically.

$$CCC = DIO + DSO - DPO$$

CCC is the cash conversion cycle in days. DIO is inventory days, DSO receivable days and DPO payable days. Use comparable periods and denominators; overdue claims still require review.

$$\text{Extra weekly cash cost} = S \times \frac{m_b - m_s}{100}$$

S is the illustrative KES weekly sales input, m_b base contribution margin and m_s downside margin, entered as percentages. This stress assumes constant sales and immediately paid variable costs; it is separate from editable baseline supplier payments.

Detailed business credit and repayment planner

$$I_j = B_j r \frac{\Delta d_j}{Y}, \quad \text{cost} = \sum_j I_j + \text{fees}$$

I_j is interest for interval j (KES), B_j its opening principal (KES), r annual nominal rate as a decimal, Δd_j actual whole days in that interval and Y the chosen 360/365 day basis. Fees are percentage-of-original-principal plus fixed KES fees.

$$N = P - \text{withheld charges}, \quad \sum_j \frac{R_j}{(1 + y)^{d_j/365}} = N$$

N is net day-zero advance and P actual original principal, both KES. R_j is the KES repayment at day d_j after draw. y is the effective annual cash-flow yield, solved from the displayed dated repayments; a 365-day year is used for this yield.

$$\text{Simple annualised cost} = \frac{\text{cost}}{P} \times \frac{365}{d}$$

P is original principal and d the facility tenor in days. This simple principal-based comparison differs from the cash-flow yield and is not a regulatory APR.

Unicode exception (retained verbatim)

$FV = PV \times (1 + r)^n$. σ^2 is variance.
